

Thermography and Arc Flash

The first rule in any health and safety situation is the elimination of risk, Personal Protection equipment (PPE) should always be the last resort.

The use of Infrared inspection windows in any thermography program eliminates the risks associated with live inspections by ensuring that thermographers are not exposed to any energized components and as such can complete the infrared survey with minimum disruption to plant and services in standard workplace PPE.

By ensuring live infrared inspections are completed safely by one operator you can expect better ROI on infrared cameras and reduced risk of premature failure of plant through more frequent inspections.
